Anti-invariant $\xi^\perp$-Riemannian Submersions From Almost Hyperbolic Contact Manifolds

Mohd Danish Siddiqi* and Mehmet Akif Akyol

(Communicated by Krishan Lal Duggal)

ABSTRACT

In this paper, we introduce anti-invariant $\xi^\perp$-Riemannian submersions from almost hyperbolic contact manifolds onto Riemannian manifolds. Necessary and sufficient conditions for a special anti-invariant $\xi^\perp$-Riemannian submersion to be totally geodesic are studied. Moreover, we obtain decomposition theorems for the total manifold of such submersions.

Keywords: Riemannian submersion; Anti-invariant $\xi^\perp$-Riemannian submersions; Trans Hyperbolic Sasakian manifold; Integrability Conditions.

AMS Subject Classification (2010): Primary: 53C25; Secondary: 53C20; 53C50; 53C40.

1. Introduction

The geometry of Riemannian submersions between Riemannian manifolds has been intensively studied and several results has been published (see O’Neil [10] and Gray [7]). In [19] Waston defined almost Hermitian submersion between almost Hermitian manifolds and in most cases he show that the base manifold and each fiber has the same kind of structure as the total space. He also show that the vertical and horizontal distributions are invariant. On the other hand, the geometry of anti-invariant Riemannian submersions is different from the geometry of almost Hermitian submersions. For example, since every holomorphic map between Kahler manifolds is harmonic [4], it follows that any holomorphic submersion between Kahler manifolds is harmonic. However, this result is not valid for anti-invariant Riemannian submersions, which was first studied by Sahin in [14] (see also [1], [2], [6], [11], [15], [16], [17]). Similarly, Ianus and Pastore [8] shows $\phi$-holomorphic maps between contact manifolds are harmonic. This implies that any contact submersion is harmonic. However, this result is not valid for anti-invariant Riemannian submersions. In [3], Chinea defined almost contact Riemannian submersion between almost contact metric manifolds. In [9], Lee studied the vertical and horizontal distribution are $\phi$-invariant. Moreover, the characteristic vector field $\xi$ is horizontal. We note that only $\phi$-holomorphic submersions have been consider on an almost contact manifolds [5]. It was 1976, Upadhyay and Dube [18] introduced the notion of almost hyperbolic contact $(f, g, \eta, \xi)$-structure. Siddiqi et. al., study some properties of $CR$-submanifolds of trans hyperbolic Sasakian manifold were studied in [12]. Recently in 2018, Siddiqi and Akyol also, study anti-invariant $\xi^\perp$-Riemannian submersions from hyperbolic $\beta$-Kenmotsu manifolds [13]. In this paper, we consider a Riemannian submersion from an almost hyperbolic contact manifold under the assumption that the fibers are anti-invariant with respect to the tensor field of type $(1, 1)$ of almost hyperbolic contact manifold. This assumption implies that the horizontal distribution is not invariant under the action of tensor field of the total manifold of such submersions. In other words, almost hyperbolic contact are useful for describing the geometry of base manifolds, anti-invariant submersion are however served to determine the geometry of total manifold.

The paper is organized as follows: In Section 2, we present the basic information needed for this paper. In Section 3, we give the definition of anti-invariant $\xi^\perp$-Riemannian submersions. We also introduce a special anti-invariant $\xi^\perp$-Riemannian submersions and obtain necessary and sufficient conditions for such submersions to be totally geodesic or harmonic. In Section 4, we give decomposition theorems by using the existence of anti-invariant $\xi^\perp$-Riemannian submersions and observe that such submersion put some restrictions on the geometry of the total manifold.

2. Preliminaries

In this section, we define almost hyperbolic contact manifolds, recall the notion of Riemannian submersions between Riemannian manifolds and give a brief review of basic facts if Riemannian submersions.

Let \( M \) be an almost hyperbolic contact metric manifold with an almost hyperbolic contact metric structure \((\phi, \xi, \eta, g_M)\), where \( \phi \) is a \((1,1)\) tensor field, \( \xi \) is a vector field, \( \eta \) is a 1-form and \( g_M \) is a compatible Riemannian metric on \( M \) such that

\[
\phi^2 = I - \eta \otimes \xi, \quad \phi \xi = 0, \quad \eta \circ \phi = 0, \quad \eta(\xi) = 1, \quad (2.1)
\]

\[
g_M(\phi X, \phi Y) = -g_M(X, Y) - \eta(Y)\eta(X) \quad (2.2)
\]

\[
g_M(X, \phi Y) = -g_M(\phi X, Y), \quad g_M(X, \xi) = \eta(X) \quad (2.3)
\]

An almost hyperbolic contact metric structure \((\phi, \xi, \eta, g_M)\) on \( M \) is called trans-hyperbolic Sasakian [12] if and only if

\[
(\nabla_X \phi) Y = \alpha(g(X, Y)\xi - \eta(Y)\phi X) + \beta(g(\phi X, Y) - \eta(Y)\phi X) \quad (2.4)
\]

for all \( X, Y \) tangent to \( M \), \( \alpha \) and \( \beta \) are smooth functions on \( M \). On a trans-hyperbolic Sasakian manifold \( M \), we have

\[
\nabla_X \xi = -\alpha(\phi X) + \beta(X - \eta(X)\xi), \quad (2.5)
\]

where \( \nabla \) is the Riemannian connection of Levi-Civita covariant differentiation.

Let \((M^m, g_M)\) and \((N^n, g_N)\) be Riemannian manifolds, where \( \dim M = m \), \( \dim N = N \) and \( m > n \). A Riemannian submersion \( F : M \to N \) is a map from \( M \) onto \( N \) satisfying the following axioms:

1. \( F \) has maximal rank
2. The differential \( F_* \) preserves the lengths of horizontal vectors.

For each \( q \in N \), \( F^{-1}(q) \) is an \((m-n)\)-dimensional submanifold of \( M \). The submanifold \( F^{-1}(q) \) are called fibers. A vector field on \( M \) is called vertical if it is always tangent to fibers. A vector field on \( M \) is called horizontal if it is always orthogonal to fibers. A vector field \( X \) on \( M \) is called basic if \( X \) is horizontal and \( F \)-related to a vector field \( X_* \) on \( N \), i.e., \( F_* X_p = X_* F(p) \) for all \( p \in M \). Note that we denote the projection morphisms on the distributions \( \ker F \) and \( \ker F_* \) by \( V \) and \( H \), respectively.

We recall the following lemma from O'Neill [10].

**Lemma 2.1.** Let \( F : M \to N \) be a Riemannian submersion between Riemannian manifolds and \( X, Y \) be basic vector fields of \( M \). Then

1. \( g_M(X, Y) = g_N(X_*, Y_*) \circ F \).
2. The horizontal part \([X, Y]^H\) of \([X, Y]\) is a basic vector field and corresponds to \([X_*, Y_*]\), i.e., \( F_*([X, Y]) = [X_*, Y_*] \).
3. \([V, X]\) is vertical for any vector field \( V \) of \( \ker F_* \).
4. \(((\nabla)^M_X Y)^H\) is the basic vector field corresponding to \( \nabla^N_{X_*} Y_* \).

The geometry of Riemannian submersion is characterized by O'Neill’s tensor \( \tau \) and \( A \) defined for vector fields \( E, F \) on \( M \) by

\[
A E F = H \nabla_{HV} V F + V \nabla_{HE} HF \quad (2.6)
\]

\[
T E F = H \nabla_{VE} V F + V \nabla_{VE} HF \quad (2.7)
\]

where \( \nabla \) is the Levi-Civita connection of \( g_M \). It is easy to see that a Riemannian submersion \( F : M \to N \) has totally geodesic fibers if and only if \( T \) vanishes identically. For any \( E \in (TM), T_C = T_{VC} \) and \( A \) is horizontal, \( A = A_{HE} \). We note that the tensor \( T \) and \( A \) satisfy

\[
T_{U W} = T_{W U}, \quad U, W \in (\ker F_*) \quad (2.8)
\]
\[ A_X Y = -A_Y X = \frac{1}{2} V[X, Y], \quad X, Y \in (\ker F)^\perp \]  

(2.9)

On the other hand, from (2.6) and (2.7), we have

\[ \nabla_V W = T_V W + \bar{\nabla}_V W \]  

(2.10)

\[ \nabla_V X = H \nabla_V X + T_Y X \]  

(2.11)

\[ \nabla_X V = A_X V + V \nabla_X V \]  

(2.12)

\[ \nabla_X Y = H \nabla_X Y + A_X V \]  

(2.13)

for \( X, Y \in (\ker F)^\perp \) and \( V, W \in (\ker F) \), where \( \nabla_V W = V \nabla_V W \). If \( X \) is basic then \( H \nabla_V X = A_X V \).

Finally, we recall the notion of harmonic maps between Riemannian manifolds. Let \((M, g_M)\) and \((N, g_N)\) be Riemannian manifolds and supposed that \( F : M \to N \) is a smooth map. Then the differential \( \phi_* \) of \( \phi \) can be viewed a section of the bundle \( \text{Hom}(TM, \phi^{-1}TN) \to M \), where \( \phi^{-1}TN \) is the pullback bundle which has fibers \((\phi^{-1}TN)_p = T_{\phi(p)}N, p \in M \). \( \text{Hom}(TM, \phi^{-1}TN) \) has a connection \( \bar{\nabla} \) induced from the Levi-Civita connection \( \nabla^M \) and the pullback connection \( \nabla^\phi \).

Then the second fundamental form of \( \phi \) is given by

\[ \langle \nabla \phi^*(X, Y) \rangle = \nabla^\phi_X \phi^*(Y) - \phi^* \langle \nabla^M_X Y \rangle \]  

(2.14)

for \( X, Y \in TM \). It is known that the second fundamental form is symmetric. A smooth map \( \phi : (M, g_M) \to (N, g_N) \) is said to be harmonic if \( \text{trace}(\nabla \phi^*) = 0 \). On the other hand, the tensor field of \( \phi \) is the section \( \tau(\phi) \) of \((\phi^{-1}TN)\) defined by

\[ \tau(\phi) = \text{div} \phi^* = m \sum_{i=1}^m (\nabla \phi^*)(e_i, e_i), \]  

(2.15)

where \( \{e_1, \ldots, e_m\} \) is the orthogonal frame on \( M \). Then it follows that \( \phi \) is harmonic if and only if \( \tau(\phi) = 0 \) (see \[10]\).

3. **Anti-invariant \( \xi^\perp \)-Riemannian Submersions**

In this section, we define anti-invariant \( \xi^\perp \)-Riemannian submersions from almost hyperbolic contact metric manifold onto a Riemannian manifold and investigate the integrability of distributions and obtain a necessary and sufficient condition for such submersions to be totally geodesic map. We also investigate the harmonincness of a special Riemannian submersions.

**Definition 3.1.** Let \((M, g_M, \phi, \xi, \eta)\) be an almost hyperbolic contact metric manifold and \((N, g_N)\) a Riemannian manifold. Suppose that there exists a Riemannian submersion \( F : M \to N \) such that \( \xi \) is normal to \( \ker F_* \) and \( \ker F_* \) is anti-invariant with respect to \( \phi \), i.e., \( \phi(\ker F_*) \subset (\ker F_*)^\perp \). Then we say that \( F \) is an anti-invariant \( \xi^\perp \)-Riemannian submersion.

Now, we assume that \( F : (M, g_M, \phi, \xi, \eta) \to (N, g_N) \) is an anti-invariant \( \xi^\perp \)-Riemannian submersion. First of all, from Definition 3.1, we have \((\ker F_*)^\perp \cap (\ker F_*) \neq 0 \). We denote the complementary orthogonal distribution to \( \phi(\ker F_*) \) in \((\ker F_*)^\perp \) by \( \mu \). Then we have

\[ (\ker F_*)^\perp = \phi(\ker F_*) \oplus \mu, \]  

(3.1)

where \( \phi(\mu) \subset \mu \). Hence \( \mu \) contains \( \xi \). Thus, for \( X \in (\ker F_*)^\perp \), we have

\[ \phi X = B X + C X, \]  

(3.2)

where \( B X \in (\ker F_*) \) and \( C X \in (\mu) \). On the other hand, since \( F_*(\ker F_*)^\perp = TN \) and \( F \) is a Riemannian submersion, using (3.2), we have

\[ g_N(F_*\phi V, F_*\phi(C X)) = 0 \]

for any \( X \in (\ker F_*)^\perp \) and \( V \in (\ker F_*) \), which implies

\[ TN = F_*(\phi(\ker F_*) \oplus F_*(\mu)). \]
Example 3.1. Let us consider a 5-dimensional manifold $M = \{(x_1, x_2, x_3, x_4, z) \in \mathbb{R}^5 : z \neq 0\}$, where $(x_1, x_2, x_3, x_4, z)$ are standard coordinates in $\mathbb{R}^5$. We choose the vector fields

$$E_1 = e^{-z} \frac{\partial}{\partial x_1}, E_2 = e^{-z} \frac{\partial}{\partial x_2}, E_3 = e^{-z} \frac{\partial}{\partial x_3}, E_4 = e^{-z} \frac{\partial}{\partial x_4}, E_5 = e^{-z} \frac{\partial}{\partial x_5},$$

which are linearly independent at each point of $M$. We define $g$ by

$$g = e^{2z}G,$$

where $G$ is the Euclidean metric on $\mathbb{R}^5$. Hence $\{E_1, E_2, E_3, E_4, E_5\}$ is an orthonormal basis of $M$. We consider an 1-form $\eta$ defined by

$$\eta = e^{2z}dz, \quad \eta(X) = g(X, E_5), \quad \forall X \in T\bar{M}.$$

We defined the $(1, 1)$ tensor field $\phi$ by

$$\phi = \left\{ \sum_{i=2}^{2} \left( x_i \frac{\partial}{\partial x_i} + z \frac{\partial}{\partial z} \right) \right\} = \sum_{i=2}^{2} \left( x_i \frac{\partial}{\partial x_i} - x_i \frac{\partial}{\partial z} \right).$$

Thus, we have

$$\phi(E_1) = E_3, \quad \phi(E_2) = E_4, \quad \phi(E_3) = -E_1, \quad \phi(E_4) = -E_2, \quad \phi(E_5) = 0.$$ 

The linear property of $g$ and $\phi$ yields that

$$\eta(E_5) = 1, \quad \phi^2(X) = X - \eta(X)E_5$$

$$g(\phi X, \phi Y) = -g(X, Y) - \eta(X)\eta(Y),$$

for any vector fields $X, Y$ on $M$. Thus, $M(\phi, \xi_1, \eta, g)$ defines an almost hyperbolic contact metric manifold with $\xi = E_5$. Moreover, let $\nabla$ be the Levi-Civita connection with respect to metric $g$. Then we have $[E_1, E_2] = 0$. Similarly $[E_1, \xi] = e^{-2z}E_1$, $[E_2, \xi] = e^{-2z}E_2$, $[E_3, \xi] = e^{-2z}E_3$.

The Riemannian connection $\nabla$ of the metric $g$ is given by

$$2g(\nabla_X Y, Z) = Xg(Y, Z) + Yg(Z, X) - Zg(X, Y) - g(X, [Y, Z]) - g(Y, [X, Z]) + g(Z, [X, Y]),$$

By Koszul’s formula, we obtain the following equations

$$\nabla_{E_1}E_1 = -e^{-z}\xi, \quad \nabla_{E_2}E_2 = -e^{-z}\xi, \quad \nabla_{E_3}E_3 = -e^{-z}\xi,$$

$$\nabla_{E_4}E_4 = -e^{-z}\xi, \quad \nabla_{E_5}E_5 = 0, \quad \nabla_{E_1}E_i = e^{-z}E_i, \quad 1 \leq i \leq 4$$

and $\nabla_{E_i}E_i = 0$ for all $1 \leq i, j \leq 4$. Thus, we see that $M$ is a trans-hyperbolic Sasakian manifold of type $(0, e^{-z})$. Here $\alpha = 0$ and $\beta = e^{-z}$.

Now, we define $(1, 1)$ tensor field as follows

$$\phi(x_1, x_2, x_3, x_4, z) = (-x_3, -x_4, x_1, x_3, z).$$

Now, we can give the following example.

Example 3.2. Let $(M_1, g_1 = e^{2z}G, \phi, \xi, \eta)$ be an almost Hyperbolic contact manifolds and $M_2$ be $\mathbb{R}^3$. The Riemannian metric tensor field $g_2$ is defined by $g_2 = e^{2z}(dy_1 \otimes dy_1 + dy_2 \otimes dy_2 + dy_3 \otimes dy_3)$ on $M_2$.

Let $\phi$ be a submersion defined by

$$\phi : \mathbb{R}^5 \rightarrow \mathbb{R}^3$$

$$(x_1, x_2, x_3, x_4, z) \mapsto \left(\frac{x_1 + x_3}{\sqrt{2}}, \frac{x_1 + x_2}{\sqrt{4}}, z\right)$$

Then it follows that

$$\ker \phi_* = \text{span} \{V_1 = \partial x_1 - \partial x_3, \quad V_2 = \partial x_2 - \partial x_4\}$$

and

$$(\ker \phi_*)^\perp = \text{span} \{X_1 = \partial x_1 + \partial x_3, \quad X_2 = \partial x_2 + \partial x_4, \quad X_3 = z = \xi\}$$
Hence we have $\phi V_1 = X_1$ and $\phi V_2 = X_2$. It means that $\phi(\ker F) \subset (\ker F)^\perp$. A straight computations, we get $\phi * X_1 = \partial_Y, \phi * X_2 = \partial_Y$ and $\phi * X_3 = \partial_Y$. Hence, we have

$$g_1(X_i, X_i) = g_2(\phi * X_i, \phi * X_i), \quad \text{for} \quad i = 1, 2, 3.$$ 

Thus $\phi$ is an anti-invariant $\xi^\perp$-Riemannian submersion.

**Lemma 3.1.** Let $F$ be an anti-invariant $\xi^\perp$-Riemannian submersion from a trans-hyperbolic Sasakian manifold $(M, g_M, \phi, \xi, \eta)$ onto a Riemannian manifold $(N, g_N)$. Then we have

$$g_M(CY, \phi V) = 0,$$

and

$$g_M(\nabla_X CY, \phi V) = -g_M(CY, \phi A_X V)$$

for $X, Y \in ((ker F_\perp)^\perp)$ and $V \in (ker F_\perp)$.

**Proof.** For $Y \in ((ker F_\perp)^\perp)$ and $V \in (ker F_\perp)$, using (2.2), we have

$$g_M(CY, \phi V) = g_M(\phi Y - BY, \phi V) = g_M(\phi Y, \phi V) = -g_M(Y, V) = 0$$

since $BY \in (ker F_\perp)$ and $\phi V, \xi \in ((ker F_\perp)^\perp)$. Differentiating (3.3) with respect to $X$, we get

$$g_M(\nabla_X CY, \phi V) = -g_M(CY, \nabla_X \phi V)$$

$$= g_M(CY, (\nabla_X \phi) V) - g_M(CY, \phi(\nabla_X V))$$

$$= -g_M(CY, \phi(\nabla_X V))$$

$$= -g_M(CY, \phi A_X V) - g_M(CY, \phi \nu \nabla_X V)$$

due to $\phi \nu \nabla_X V \in (ker F_\perp)$. Our assertion is complete. 

We study the integrability of the distribution $(ker F_\perp)^\perp$ and then we investigate the geometry of leaves of $ker F_\perp$ and $(ker F_\perp)^\perp$. We note it is known that the distribution $(ker F_\perp)$ is integrable.

**Theorem 3.1.** Let $F$ be an anti-invariant $\xi^\perp$-Riemannian submersion from a trans-hyperbolic Sasakian manifold $(M, g_M, \phi, \xi, \eta)$ onto a Riemannian manifold $(N, g_N)$. The followings are equivalent.

1. $(ker F_\perp)^\perp$ is integrable,

2. 

$$g_N((\nabla F_\perp)(BY, BX), F_\perp V) = g_N((\nabla F_\perp)(X, BY), F_\perp V)$$

$$+ g_M(CY, \phi A_X V) - g_M(CX, \phi A_Y V)$$

$$+ (\alpha + \beta)\eta(Y)g_M(X, V) - (\alpha + \beta)\eta(X)g_M(Y, V),$$

3. 

$$g_M(A_X BY - A_Y BY, \phi V) = g_M(CY, \phi A_X V) - g_M(CX, \phi A_Y V)$$

$$+ (\alpha + \beta)\eta(Y)g_M(X, V) - (\alpha + \beta)\eta(X)g_M(Y, V).$$

for $X, Y \in (ker F_\perp)^\perp$ and $V \in (ker F_\perp)$.

**Proof.** For $Y \in (ker F_\perp)^\perp$ and $V \in (ker F_\perp)$, from Definition 3.1, $\phi V \in (ker F_\perp)^\perp$ and $\phi Y \in (ker F_\perp) \oplus \mu$. Using (2.2) and (2.4), we note that for $X \in (ker F_\perp)^\perp$,

$$g_M(\nabla_X V, Y) = g_M(\nabla_X \phi Y, \phi V) - (\alpha + \beta)\eta(Y)g_M(X, V)$$

$$- (\alpha + \beta)\eta(X)\eta(Y)\eta(V).$$

Therefore, from (3.5), we get

$$g_M([X, Y], V) = g_M(\nabla_X \phi Y, \phi V) - g_M(\nabla Y \phi X, \phi V)$$
Corollary 3.1. Let $F$ be an anti-invariant $\xi^\perp$-Riemannian submersion from a trans-hyperbolic Sasakian manifold $(M, g_M, \phi, \xi, \eta)$ onto a Riemannian manifold $(N, g_N)$ with $(\ker F^\perp) \oplus \phi(\ker F^\perp) \perp \xi >$. Then the following are equivalent.

1. $(\ker F^\perp) \perp$ is integrable
2. $(\nabla F^\perp)(X, \phi Y) + (\alpha + \beta)\eta(X)F^\perp Y = (\nabla F^\perp)(Y, \phi X) + (\alpha + \beta)\eta(Y)F^\perp X$
3. $A_X \phi Y + (\alpha + \beta)\eta(X)Y = A_Y \phi X + (\alpha + \beta)\eta(Y)X$, for $X, Y \in (\ker F^\perp) \perp$.

Theorem 3.2. Let $F$ be an anti-invariant $\xi^\perp$-Riemannian submersion from a trans-hyperbolic Sasakian manifold $(M, g_M, \phi, \xi, \eta)$ onto a Riemannian manifold $(N, g_N)$. The following are equivalent.

1. $(\ker F^\perp) \perp$ defines a totally geodesic foliation on $M$.
2. $g_M(A_XBY, \phi V) = g_M(CY, \phi AX Y) - (\alpha + \beta)\eta(X)g_M(X, V) - (\alpha + \beta)\eta(X)g_M(Y, V)$
3. $g_N((\nabla F^\perp)(Y, \phi X), F^\perp X) = g_M(CY, \phi AX Y) - (\alpha + \beta)\eta(X)g_M(X, V) - (\alpha + \beta)\eta(X)g_M(Y, V)$, for $X, Y \in (\ker F^\perp) \perp$ and $V \in (\ker F^\perp) \perp$.

Proof. For $X, Y \in (\ker F^\perp) \perp$ and $V \in (\ker F^\perp) \perp$, from (3.5), we have

$$g_M(\nabla_X Y, V) = g_M(A_X BY, \phi V) + g_M(\nabla_X CY, \phi V) - (\alpha + \beta)\eta(Y)g_M(X, V) - (\alpha + \beta)\eta(X)\eta(Y)\eta(V)$$

Then from (3.4), we have

$$g_M(\nabla_X Y, V) = g_M(A_X BY, \phi V) + g_M(CY, \phi AX Y) - (\alpha + \beta)\eta(Y)g_M(X, V) - (\alpha + \beta)\eta(X)\eta(Y)\eta(V)$$

which shows $\text{(1)} \iff \text{(2)}$. On the other hand, from (2.12) and (2.14), we have

$$g_M(A_X BY, \phi V) = g_N(\nabla F^\perp)(X, BY), F^\perp(\phi V))$$

which proves $\text{(2)} \iff \text{(3)}$. \qed
Corollary 3.2. Let $F$ be an anti-invariant $\xi^\perp$-Riemannian submersion from a trans-hyperbolic Sasakian manifold $(M, g_M, \phi, \xi, \eta)$ onto a Riemannian manifold $(N, g_N)$ with $(\ker F_\ast)^\perp = \phi(\ker F_\ast)^\perp < \xi >$. Then the following are equivalent.

1. $(\ker F_\ast)^\perp$ defines a totally geodesic foliation on $M$
2. $A_X \phi Y = (\alpha + \beta)\eta(Y)X - (\alpha + \beta)\eta(X)Y$
3. $(\nabla F_\ast)(Y, \phi X) = (\alpha + \beta)\eta(Y)F_\ast X - (\alpha + \beta)\eta(X)F_\ast Y$

for $X, Y \in (\ker F_\ast)^\perp$.

Theorem 3.3. Let $F$ be an anti-invariant $\xi^\perp$-Riemannian submersion from a trans-hyperbolic Sasakian manifold $(M, g_M, \phi, \xi, \eta)$ onto a Riemannian manifold $(N, g_N)$. The following are equivalent.

1. $\ker F_\ast$ defines a totally geodesic foliation on $M$
2. $-g_N(\nabla F_\ast)(V, \phi X, F_\ast W) = 0$
3. $T_V B X + A_{CX} V \in (\mu)$,

for $X, \in (\ker F_\ast)^\perp$ and $V, W \in (\ker F_\ast)$

Proof. For $X, \in (\ker F_\ast)^\perp$ and $V, W \in (\ker F_\ast)$, $g_M(W, \xi) = 0$ implies that from (2.4)

$$g_M(\nabla V W, \xi) = -g_M(W, \nabla V \xi) = g_M(W, -\alpha \phi V + \beta (V - \eta(V) \xi)) = 0.$$ 

Thus we have

$$g_M(\nabla V W, X) = -g_M(\phi \nabla V W, \phi X) - \eta((\nabla V W)\eta(X))$$
$$= -g_M(\phi \nabla V W, \phi X)$$
$$= -g_M(\nabla V \phi W, \phi X) + g_M((\nabla V \phi) W, \phi X)$$
$$= g_M(\phi W, \nabla V \phi X).$$

Since $F$ is Riemannian submersion, we have

$$g_M(\nabla V W, X) = g_M(F_\ast \phi W, F_\ast \nabla V \phi X) = -g_N(F_\ast \phi W, (\nabla F_\ast)(\phi X)),$$

which proves $(1) \iff (2)$.

By direct calculation, we derive

$$-g_N(F_\ast \phi W, (\nabla F_\ast)(\phi X)) = g_M(\phi W, \nabla V \phi X)$$
$$= g_M(\phi W, \nabla V BX + \nabla V CX)$$
$$= g_M(\phi W, \nabla V BX + [V, CX] + \nabla CX V).$$

Since $[V, CX] \in (\ker F_\ast)$, from (2.10) and (2.12), we obtain

$$-g_N(F_\ast \phi W, (\nabla F_\ast)(\phi X)) = g_M(\phi W, T_V BX + A_{CX} V),$$

which proves $(2) \iff (3)$.

As an analouge of a Lagrangian Riemannian submersion in [11], we have a similar result;

Corollary 3.3. Let $F$ be an anti-invariant $\xi^\perp$-Riemannian submersion from a trans-hyperbolic Sasakian manifold $(M, g_M, \phi, \xi, \eta)$ onto a Riemannian manifold $(N, g_N)$ with $(\ker F_\ast)^\perp = \phi(\ker F_\ast)^\perp < \xi >$. Then the following are equivalent.

1. $(\ker F_\ast)^\perp$ defines a totally geodesic foliation on $M$
2. $-(\nabla F_\ast)(V, \phi X) = 0$
3. $T_V \phi W = 0$. 

www.iejgeo.com
\( X, \in (\ker F^\ast)^\perp \) and \( V, W \in (\ker F^\ast) \)

**Proof.** From Theorem 3.6, it is enough to show \((2) \iff (3)\). Using (2.14) and (2.11), we have

\[
-g_N(F^\ast \phi W, (\nabla F^\ast)(V \phi X)) = g_M((\nabla V \phi W) \phi X) = g_M(T_V \phi W, \phi X).
\]

Since \( T_V \phi W \in (\ker F^\ast) \), the proof is complete. \( \square \)

We note that a differentiable map \( F \) between two Riemannian manifolds is called totally geodesic if \( \nabla F^\ast = 0 \).

**Theorem 3.4.** Let \( F \) be an anti-invariant \( \xi^\perp \)-Riemannian submersion from a trans-hyperbolic Sasakian manifold \((M, g_M, \phi, \xi, \eta)\) onto a Riemannian manifold \((N, g_N)\) with \((\ker F^\ast)^\perp = \phi(\ker F^\ast) \oplus \langle \xi \rangle \). Then \( F \) is a totally geodesic map if and only if

\[
T_V \phi W = 0, \quad V, W \in (\ker F^\ast) \tag{3.6}
\]

and

\[
A_X \phi W = 0, \quad X \in (\ker F^\ast)^\perp. \tag{3.7}
\]

**Proof.** First of all, we recall that the second fundamental form of a Riemannian submersion satisfies

\[
(\nabla F^\ast)(X, Y) = 0 \quad \forall \ X, Y \in (\ker F^\ast)^\perp. \tag{3.8}
\]

For \( V, W \in (\ker F^\ast) \), we get

\[
(\nabla F^\ast)(X, Y) = F^\ast(\phi T_V \phi W). \tag{3.9}
\]

On the other hand, from (2.1), (2.2) and (2.14), we have

\[
(\nabla F^\ast)(X, W) = F^\ast(\phi A_X \phi W), \quad X \in (\ker F^\ast)^\perp. \tag{3.10}
\]

Therefore, \( F \) is totally geodesic if and only if

\[
\phi(T_V \phi W) = 0 \quad \forall \ V, W \in (\ker F^\ast)^\perp. \tag{3.11}
\]

and

\[
\phi(A_X \phi W) = 0 \quad \forall \ X \in (\ker F^\ast)^\perp. \tag{3.12}
\]

From (2.2), (2.6) and (2.7), we have

\[
T_V \phi W = 0 \quad \forall \ V, W \in (\ker F^\ast). \tag{3.13}
\]

and

\[
A_X \phi W = 0 \quad \forall \ X \in (\ker F^\ast)^\perp. \tag{3.14}
\]

From (2.4), \( F \) is totally geodesic if and only the equation (3.6) and (3.7) hold \( \square \)

Finally, in this section, we give a necessary and sufficient condition for a special Riemannian submersion to be harmonic as an analogue of Lagrangian Riemannian submersion in [11].

**Theorem 3.5.** Let \( F \) be an anti-invariant \( \xi^\perp \)-Riemannian submersion from a trans-hyperbolic Sasakian manifold \((M, g_M, \phi, \xi, \eta)\) onto a Riemannian manifold \((N, g_N)\) with \((\ker F^\ast)^\perp = \phi(\ker F^\ast) \oplus \langle \xi \rangle \). Then \( F \) is harmonic if and only if \( \text{Trace}(\phi T_V) = 0 \) for \( V \in (\ker F^\ast) \).

**Proof.** From [5], we know that \( F \) is harmonic if and only if \( F \) has minimal fibers. Thus \( F \) is harmonic if and only if \( \sum_{i=1}^{m_1} T_{e_i} = 0 \). On the other hand, from (2.4), (2.11) and (2.10), we have

\[
T_V \phi W = \phi T_V W \tag{3.14}
\]

due to \( \xi \in (\ker F^\ast)^\perp \) for any \( V, W \in (\ker F^\ast) \). Using (3.14), we get

\[
\sum_{i=1}^{m_1} g_M(T_{e_i} \phi e_i, V) = \sum_{i=1}^{m_1} g_M(\phi T_{e_i} \phi e_i, V) = -\sum_{i=1}^{m_1} g_M(T_{e_i}, \phi V)
\]

www.iejgeo.com
for any $V \in (\ker F_\ast)$. Thus skew-symmetric $T$ implies that

$$\sum_{i=1}^{m_1} g_M(\phi T_{e_i} e_i, V) = -\sum_{i=1}^{m_1} g_M(T_{e_i} e_i, \phi V).$$

Using (2.8) and (2.2), we have

$$\sum_{i=1}^{m_1} g_M(e_i, \phi T_{e_i} e_i) = -\sum_{i=1}^{m_1} g_M(\phi e_i, T_{e_i} e_i) = -\sum_{i=1}^{m_1} g_M(T_{e_i} e_i, \phi V)$$

which shows our assertion.

\[\square\]

4. Decomposition theorems

In this section, we obtain decomposition theorems by using the existence of anti-invariant $\xi^\perp$-Riemannian submersions. First, we recall the following.

**Theorem 4.1.** [10] Let $g$ be a Riemannian metric on the manifold $B = M \times N$ and assume that the canonical foliations $D_M$ and $D_N$ intersect perpendicular everywhere. Then $g$ is the metric tensor of

1. (i) a twisted product $M \times_f N$ if and only if $D_M$ is a totally geodesic foliation and $D_N$ is a totally umbilical foliation.
2. (ii) a warped product $M \times_f N$ if and only if $D_M$ is a totally geodesic foliation and $D_N$ is a spheric foliation, i.e., it is umbilical and its mean curvature vector field is parallel.
3. (iii) a usual product of Riemannian manifold if and only if $D_M$ and $D_N$ are totally geodesic foliations.

Our first decomposition theorem for anti-invariant $\xi^\perp$-Riemannian submersion comes from Theorem 3.4 and 3.6 in terms of the second fundamental forms of such submersions.

**Theorem 4.2.** Let $F$ be an anti-invariant $\xi^\perp$-Riemannian submersion from a trans-hyperbolic Sasakian manifold $(M, g_M, \phi, \xi, \eta)$ on to a Riemannian manifold $(N, g_N)$. Then $M$ is locally product manifold if and only if

$$-g_N((\nabla F_\ast)(Y, \phi X), F_\ast \phi V) = g_M(C Y, \phi A X V) - (\alpha + \beta) \eta(Y) g_M(X, V)$$

and

$$-g_N((\nabla F_\ast)(V, \phi X), F_\ast \phi W) = 0$$

for $X, Y \in (\ker F_\ast)^\perp$ and $V, W \in (\ker F_\ast)$.

From Corollary 3.5 and 3.7, we have the following decomposition theorem:

**Theorem 4.3.** Let $F$ be an anti-invariant $\xi^\perp$-Riemannian submersion from a trans-hyperbolic Sasakian manifold $(M, g_M, \phi, \xi, \eta)$ on to a Riemannian manifold $(N, g_N)$ with $(\ker F_\ast)^\perp \not\subset \xi$. Then $M$ is a locally product manifold if and only if $AX \phi Y = (\alpha + \beta) \eta(Y) X$ and $TV \phi W = 0$, for $X, Y \in (\ker F_\ast)^\perp$ and $V, W \in (\ker F_\ast)$.

Next we obtain a decomposition theorem which is related to the notion of a twisted product manifold.

**Theorem 4.4.** Let $F$ be an anti-invariant $\xi^\perp$-Riemannian submersion from a trans-hyperbolic Sasakian manifold $(M, g_M, \phi, \xi, \eta)$ on to a Riemannian manifold $(N, g_N)$ with $(\ker F_\ast)^\perp \not\subset \xi$. Then $M$ is locally twisted product manifold of the form $M_{ker F_\ast} \times_f M_{ker F_\ast}$ if and only if

$$TV \phi X = -g_M(X, TV V) \| V \|^2 - (\alpha + \beta) \eta(Y) g_M(\phi X, \phi V).$$

and

$$AX \phi Y = (\alpha + \beta) \eta(Y) X$$

for $X, Y \in (\ker F_\ast)^\perp$ and $V \in (\ker F_\ast)$, where $M_{(\ker F_\ast)}$ and $M_{(\ker F_\ast)}$ are integrable manifolds of the distributions $(\ker F_\ast)^\perp$ and $(\ker F_\ast)$. 

www.iejgeo.com
Proof. For \( X \in (\ker F^*_+) \) and \( V \in (\ker F^*_+) \), from (2.4) and (2.11), we obtain
\[
g_M(\nabla_V W, X) = g_M(T_V \phi W, \phi X) = -g_M(\phi W, T_V \phi X)
\]
Since \( T_V \) is skew-symmetric. This implies that \( \ker F^*_+ \) is totally umbilical if and only if
\[
T_V \phi X - (\alpha + \beta) \eta(V) g_M(\phi X, \phi V) = -X(\lambda) \phi V,
\]
where \( \lambda \) is a function on \( M \). By direct computation,
\[
T_V \phi X = -g_M(X, T_V V) \|V\|^2 - (\alpha + \beta) \eta(Y) g_M(\phi X, \phi V).
\]

Then the proof follows from Corollary 3.5

**Theorem 4.5.** Let \((M, g_M, \phi, \xi, \eta)\) be a trans-hyperbolic Sasakian manifold and \((N, g_N)\) be a Riemannian manifold. Then there does not exist an anti-invariant \( \xi^\perp \)-Riemannian submersion from \( M \) to \( N \) with \((\ker F^*_+)^\perp = \phi(\ker F^*_+) \perp < \xi \) such that \( M \) is a locally proper twisted product manifold of the form \( M_{\ker F^*_+} \times_f M_{(\ker F^*_+)^\perp} \).

**Proof.** Suppose that \( F : (M, g_M, \phi, \xi, \eta) \rightarrow (N, g_N) \) is an anti-invariant \( \xi^\perp \)-Riemannian submersion with \((\ker F^*_+)^\perp = \phi(\ker F^*_+) \perp < \xi \) and \( M \) is a locally twisted product of the form \( M_{\ker F^*_+} \times_f M_{(\ker F^*_+)^\perp} \). Then \( M_{\ker F^*_+} \) is a totally geodesic foliation and \( M_{(\ker F^*_+)^\perp} \) is a totally umbilical foliation. We denote the second fundamental form of \( M_{(\ker F^*_+)^\perp} \) by \( h \). Then we have
\[
g_M(\nabla_X Y, V) = g_M(h(X, Y), V) \quad X, Y \in ((\ker F^*_+)^\perp, V \in (\ker F^*_+)). \tag{4.1}
\]
Since \( M_{(\ker F^*_+)^\perp} \) is a totally umbilical foliation, we have
\[
g_M(\nabla_X Y, V) = g_M(H, V) g_M(X, Y),
\]
where \( H \) is the mean curvature vector field of \( M_{(\ker F^*_+)^\perp} \). On the other hand, from (3.5), we derive
\[
g_M(\nabla_X Y, V) = -g_M(\phi Y, \nabla_X \phi V) - (\alpha + \beta) \eta(Y) g(X, V) - (\alpha + \beta) \eta(Y) g(X, \phi V). \tag{4.2}
\]
Using (2.13), we obtain
\[
g_M(\nabla_X Y, V) = g_M(\phi Y, A_X \phi V) - (\alpha + \beta) \eta(Y) g(X, V) - (\alpha + \beta) \eta(Y) g(X, \eta(V) \xi). \tag{4.3}
\]
Therefore, from (4.1), (4.3) and (2.2), we have
\[
A_X \phi V = g_M(H, V) \phi X + \eta(A_X \phi V) \xi.
\]
Since \( A_X \phi V \in (\ker F^*_+) \),
\[
\eta(A_X \phi V) = g_M(A_X \phi V, \xi) = 0.
\]
Thus, we have
\[
A_X \phi V = g_M(H, V) \phi X.
\]
Hence, we derive
\[
g_M(A_X \phi V, \phi X) - (\alpha + \beta) \eta(Y) \eta(Y) g(Y, \phi X) = -g_M(H, V) \left\{ \|X\|^2 - \eta^2(X) \right\}
\]
\[
g_M(\nabla_X \phi V, \phi X) = -g_M(H, V) \left\{ \|X\|^2 - \eta^2(X) \right\} + (\alpha + \beta) \eta(Y) \eta(Y) g(Y, \phi X)
\]
\[
g_M(\nabla_X Y, V) + (\alpha + \beta) \eta(Y) g(X, V) - (\alpha + \beta) \eta(Y) \eta(Y) g(V, \phi X)
\]
\[
= -g_M(H, V) \left\{ \|X\|^2 - \eta^2(X) \right\} + (\alpha + \beta) \eta(Y) \eta(Y) g(V, \phi X).
\]
Thus using (2.9), we have \( A_X X = 0 \), which implies
\[
(\alpha + \beta) \eta(Y) g_M(X, V) = -g_M(H, V) \left\{ \|X\|^2 - \eta^2(X) \right\} + (\alpha + \beta) \eta(Y) g(Y, \eta(V) - g_M(Y, \phi X))
\]
for every \( X \in ((\ker F^*_+)^\perp, V \in (\ker F^*_+)) \). Choosing \( X \) which is orthogonal to \( \xi \), \( g_M(H, V) \|X\|^2 = 0 \). Since \( g_M \) is the Riemannian metric and \( H \in (\ker F^*_+) \), we conclude that \( H = 0 \), which shows \( \ker F^*_+ \) is totally geodesic, so \( M \) is usual product of Riemannian manifolds. \( \square \)
